1. $N = 2$ Supergravity

1.1 Supersymmetric multiplets

We consider $D = 4$, $N = 2$ supergravity. The supersymmetric multiplets with spin less or equal than 2 are,

- One gravity multiplet, containing the graviton $g_{\mu\nu}$, two gravitini ψ_μ^α and one Abelian gauge field \mathcal{A}_μ known as the graviphoton.

$$\left(-2, -\frac{3^2}{2}, -1\right) + \left(+1, +\frac{3^2}{2}, +2\right) \quad (1.1)$$

- n_V vector multiplet, each consisting of one Abelian gauge field A_μ , two gaugini λ^α and one complex scalar z . The complex scalars z take values in a projective special Kähler manifold \mathcal{M}_V of real dimension $2n_V$.

$$\left(-1, -\frac{1^2}{2}, 0\right) + \left(0, +\frac{1^2}{2}, +1\right), \quad n_V \text{ copies} \quad (1.2)$$

- n_H hypermultiplets, each consisting of two complex scalars and two hyperini $\psi, \tilde{\psi}$. The scalars take values in a quaternionic-Kähler space \mathcal{M}_h of real dimension $4n_H$.

$$\left(-\frac{1}{2}, 0^2, \frac{1}{2}\right) + \left(-\frac{1}{2}, 0^2, \frac{1}{2}\right), \quad n_H \text{ copies} \quad (1.3)$$

We consider the ungauged $N = 2$ supergravity, i.e., the hypermultiplets is not charged by the vector multiplets. The special geometry describes the *vector multiplet*.

1.2 Special geometry

The coupling of the vector multiplets, including the geometry of the scalar manifold \mathcal{M}_V , are conveniently described by means of a $Sp(2n_V + 2)$ principal bundle ϵ over \mathcal{M}_V , and its associated bundle ϵ_V in the vector representation of $Sp(2n_V + 2)$. The origin of the symplectic symmetry lies in electric-magnetic duality, which mixes the n_V vectors A_μ and the graviphoton \mathcal{A}_μ together with their magnetic duals. Denoting a section Ω by its coordinates (X^I, F_I) , ($I = 0, \dots, n_V + 1$), the antisymmetric product

$$\langle \Omega, \Omega' \rangle = (X^I \ F_I) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} X'^J \\ F'_I \end{pmatrix} = X^I F'_I - X'^I F_I \quad (1.4)$$

The symplectic form is $\langle d\Omega, d\Omega' \rangle = dX^I \wedge dF_I$.

The geometry of \mathcal{M}_V is completely determined by a choice of a holomorphic section $\Omega(z) = (X^I(z), F_I(z))$ taking value in a Lagrangian cone, i.e. a dilation invariant subspace such that $dX^I \wedge dF_I = 0$. The special geometry constraint is,

$$\partial_J X^I F_I - X^I \partial_J F_I = 0, \quad (1.5)$$

where $J = 1, \dots, n_V + 1$ and the derivatives are in the projective coordinates of \mathcal{M}_V . Furthermore, we may choose the

X^I as the projective coordinates, hence (1.5) is simplified to,

$$F_I = X^J \frac{\partial F_J}{\partial X^I}. \quad (1.6)$$

So we can define the prepotential $F = \frac{1}{2} X^J F_J$ such that,

$$F_I = \frac{\partial F}{\partial X^I}. \quad (1.7)$$

The prepotential is an homogeneous function of degree 2 in the X^I . The Hessian of the prepotential, $\tau_{IJ} = \partial_I \partial_J F$, is independent of X^I . Hence

$$F_I = \tau_{IJ} X^J. \quad (1.8)$$

At a generic point on \mathcal{M}_V , we can choose the *special coordinates* $z_i = X^i / X^0$ ($i = 1, \dots, n_V$) as the holomorphic coordinates for \mathcal{M}_V . Once the holomorphic section $\Omega(z)$ is given, the metric on \mathcal{M}_V is obtained from the Kähler potential,

$$\mathcal{K}(z^i, \bar{z}^i) = -\log \left(i \langle \bar{\Omega}, \Omega \rangle \right) = -\log \left(i (\bar{X}^I F_I - X^I \bar{F}_I) \right). \quad (1.9)$$

The metric

$$g_{i\bar{j}} = \partial_i \partial_{\bar{j}} \mathcal{K} = i e^{\mathcal{K}} \langle \partial_i \Omega, \bar{\partial}_{\bar{j}} \bar{\Omega} \rangle - \partial_i \mathcal{K} \bar{\partial}_{\bar{j}} \mathcal{K} \quad (1.10)$$

Under a Kähler transformation, $\Omega \rightarrow e^{f(z)}\Omega$,

$$\mathcal{K} \rightarrow \mathcal{K} - f(z) - \bar{f}(\bar{z}), \quad (1.11)$$

and the metric is invariant. We may define the rescaled holomorphic section as,

$$\tilde{\Omega} = e^{\mathcal{K}/2}\Omega, \quad (1.12)$$

which transforms by a phase, $\tilde{\Omega} \rightarrow e^{(f-\bar{f})/2}\tilde{\Omega}$ under the Kähler transformation.

The derived section is defined by $U_i = D_i\tilde{\Omega} = (f_i^I, h_{iI})$, where

$$f_i^I = e^{\mathcal{K}/2}D_iX^I = e^{\mathcal{K}/2}(\partial_iX^I + \partial_i\mathcal{K}X^I) \quad (1.13)$$

$$h_{iI} = e^{\mathcal{K}/2}D_i h_I = e^{\mathcal{K}/2}(\partial_i F_I + \partial_i\mathcal{K}F_I). \quad (1.14)$$

Hence the metric is

$$g_{i\bar{j}} = -i\langle U_i, \bar{U}_{\bar{j}} \rangle. \quad (1.15)$$

1.3 4D action

The kinetic term of the $n_V + 1$ Abelian gauge fields (including the graviphoton) is ($I = 0, \dots, n_V$),

$$\mathcal{L}_{Maxwell} = -(Im\mathcal{N}_{IJ})\mathcal{F}^I \wedge \star\mathcal{F}^J + (Re\mathcal{N}_{IJ})\mathcal{F}^I \wedge \mathcal{F}^J \quad (1.16)$$

where \mathcal{N}_{IJ} is defined to be

$$\mathcal{N}_{IJ} = \bar{\tau}_{IJ} + 2i\frac{(Im\tau \cdot X)_I(Im\tau \cdot X)_J}{X \cdot Im\tau \cdot X}. \quad (1.17)$$

which satisfies these relations,

$$F_I = \mathcal{N}_{IJ}X^J, \quad h_{iI} = \bar{\mathcal{N}}_{IJ}f_i^J. \quad (1.18)$$

Note that \mathcal{N}_{IJ} has X dependence, so the coupling constants of the 4D action depend on the vector multiplets moduli. $Im\mathcal{N}_{IJ}$ is a negative definite matrix, as required for the positive definiteness for the gauge kinetic terms.

We may absorb the Yang-Mills angle terms as,

$$\mathcal{L}_{Maxwell} = Im[\bar{\mathcal{N}}_{IJ}\mathcal{F}^{I-} \wedge \star\mathcal{F}^{J-}] \quad (1.19)$$

where $\mathcal{F}^{I-} = (\mathcal{F}^I - i\star\mathcal{F}^I)/\sqrt{2}$.

The dual field of $F^{I;\mu\nu}$ is,¹

$$\mathcal{G}_I = \frac{1}{2}\frac{\partial\mathcal{L}_{Maxwell}}{\partial\mathcal{F}^I} = (Re\mathcal{N})_{IJ}\mathcal{F}^J + (Im\mathcal{N})_{IJ}\star\mathcal{F}^J \quad (1.20)$$

¹The functional derivative should be viewed as the formal derivative in F^I , not $F^{I,\mu\nu}$.

Under the symplectic transformation,

$$\begin{pmatrix} X \\ F \end{pmatrix} \rightarrow \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} X \\ F \end{pmatrix} \quad (1.21)$$

\mathcal{N} transforms as "period matrix" $\mathcal{N} \rightarrow (C + D\mathcal{N})(A + B\mathcal{N})^{-1}$, while the field strengths $(\mathcal{F}^{I-}, G_I^- = \tilde{N}_{IJ}\mathcal{F}^{J-})$ transform as a symplectic vector,

$$\begin{pmatrix} \mathcal{F}^- \\ \mathcal{G}^- \end{pmatrix} \rightarrow \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} \mathcal{F}^- \\ \mathcal{G}^- \end{pmatrix}. \quad (1.22)$$

The 4D action can be rewritten as

$$\mathcal{L}_{Maxwell} = Im(G_I^- \wedge \star \mathcal{F}^{I-}), \quad (1.23)$$

which is invariant under the symplectic transformation.

1.4 Central charge

The field strength of the graviphoton is,

$$T_{\mu\nu}^- = -2ie^{\mathcal{K}/2} X^I (Im\mathcal{N})_{IJ} \mathcal{F}^{J-} = e^{\mathcal{K}/2} (X^I \mathcal{G}_I^- - F_I \mathcal{F}^{I-}). \quad (1.24)$$

The charges associated to $T_{\mu\nu}^-$ measured at infinity,

$$Z = e^{\mathcal{K}/2} (q_I X^I - p^I F_I), \quad (1.25)$$

is the central charge in $\mathcal{N} = 2$ supersymmetry algebra,

$$\{Q_\alpha^i, \bar{Q}_{\dot{\alpha}j}\} = P_\mu \sigma_{\alpha\dot{\alpha}}^\mu \delta_j^i, \quad \{Q_\alpha^i, Q_\beta^j\} = Z \epsilon^{ij} \epsilon_{\alpha\beta}, \quad (1.26)$$

where $i, j = 1, 2$. The BPS bound is,

$$M \geq |Z|. \quad (1.27)$$
